⁷ Summary

⁸ growpacity is a Python and C toolkit for calculating dust opacities in astrophysical environments. It provides a class (`OpacityCalculator`) for generating, storing, and interpolating ⁹ mean opacities (Rosseland and Planck) over customizable grids of grain size distributions, ¹⁰ temperature, and power-law exponents. This package is designed as a wrapper around [OpTool](#), ¹¹ allowing users to specify grain composition and obtain temperature-, maximum grain size-, ¹² and dust size distribution-dependent mean opacities. The resulting tables are lightweight and ¹³ optimized for use in radiation hydrodynamics and dust coagulation models, where grain size ¹⁴ distributions evolve dynamically.

¹⁶ Statement of need

¹⁷ Radiation hydrodynamics simulations often require a dust opacity model under the assumption of a particular grain size or size distribution. It is however not straightforward to implement a ¹⁸ dust opacity model that accounts for the dynamical evolution of this grain size distribution. ¹⁹ With growpacity, we outline a method to construct such a model and provide a python ²⁰ package that implements it. The model is a wrapper around the OpTool package, with the user ²¹ providing a grain composition and receiving temperature-, maximum grain size-, and dust size ²² distribution-dependent mean opacities, tabulated in a lightweight format and complemented ²³ with efficient interpolation methods for usage in radiation hydrodynamics simulations.

²⁵ Method

²⁶ For a given grain composition and assuming a grain size distribution with number density $n(a) \propto$ ²⁷ a^q for grains with size a between minimum and maximum grain sizes a_{\min} and a_{\max} , the [OpTool](#) ²⁸ package [[@DominikEtal:2021](#)] can compute the absorption and scattering opacities $\kappa_{\text{abs}}(\nu)$ ²⁹ and $\kappa_{\text{sca}}(\nu)$ (in cm^2/g) as well as the asymmetry factor $g(\nu)$ [[@HenyeyGreenstein:1941](#)] over ³⁰ a frequency grid ν . This calculation is done using the Distribution of Hollow Spheres method ³¹ (DHS) [[@MinEtal:2005](#)]. The Rosseland and Planck mean opacities κ_R and κ_P can then be ³² computed as

$$\kappa_P(T) = \frac{\int_0^\infty \kappa_{\text{abs}} B_\nu(T) d\nu}{\int_0^\infty B_\nu(T) d\nu}, \quad \kappa_R(T) = \frac{\int_0^\infty u_\nu(T) d\nu}{\int_0^\infty [\kappa_{\text{abs}} + (1-g) \kappa_{\text{sca}}]^{-1} u_\nu(T) d\nu}, \quad u_\nu(T) = \left. \frac{dB_\nu}{dT} \right|_T,$$

³³ where $B_\nu(T)$ is the Planck function at temperature T . By fixing the grain composition and ³⁴ a_{\min} , OpTool can be used to calculate the absorption and scattering opacities over a grid

35 of a_{\max} and q . The above equation can then be used to compute and tabulate κ_R and κ_P
 36 over a_{\max} , q , and T . The resulting 3D tables can be used in any context where a_{\max} and
 37 q are dynamically evolved according to a dust coagulation model [[@BirnstielEtal:2017](#);
 38 [@StammllerBirnstiel:2022](#); [@PfeilEtal:2024](#); [@RobinsonEtal:2024](#)].

39 Interpolation algorithm

40 Once the 3D tables of $\kappa_R(q, a_{\max}, T)$ and $\kappa_P(q, a_{\max}, T)$ have been computed, they can be
 41 interpolated within the range of tabulated values. We interpolate for $\log \kappa$ as a function of q ,
 42 $\log a_{\max}$, and $\log T$, with regular sampling in this space (i.e., logarithmic spacing for a_{\max} and
 43 T). This works best when the mean opacities follow a powerlaw with respect to temperature
 44 $\kappa \propto T^b \Rightarrow \log \kappa \propto b \log T$, which is a reasonable approximation and especially holds for small
 45 grains [[@BellLin:1994](#); [@SemenovEtal:2003](#)]. It also ensures that the interpolated opacities
 46 are always positive in case extrapolation is needed.
 47 We use a trilinear interpolation scheme, which is fast and simple to implement, and takes
 48 advantage of the fact that the arrays q , $\log a_{\max}$, and $\log T$ are sorted and regularly spaced
 49 to efficiently locate the indices of the grid points that surround the point of interest. For
 50 each array $x \in \{q, \log a_{\max}, \log T\}$ and for a target value x_t , we first find the index i such
 51 that $x_i \leq x_t < x_{i+1}$ as $i = \lfloor (x_t - x_0) \Delta x^{-1} \rfloor$, where x_0 is the first (smallest) value in the
 52 sampling space and $\Delta x = x_{i+1} - x_i$ is the (constant) sampling spacing. As this information
 53 is known *a priori*, this reduces the complexity of finding the required indices from $\mathcal{O}(\log N)$ to
 54 $\mathcal{O}(1)$, where N is the number of grid points in x , and is especially efficient for larger grids. Of
 55 course, care must be taken to ensure that the indices are within the bounds of the grid.

56 Implementation

57 The above method is implemented in the `growpacity` package. The package provides a simple
 58 python interface to `OpTool` to compute accurate dust opacities for a given grain composition
 59 (provided in `OpTool` format) and for a fixed a_{\min} , over a grid of a_{\max} , q , and T . The resulting
 60 3D tables of κ_R and κ_P are saved in binary files that can be easily loaded with python. We
 61 also provide an implementation of the interpolating function in C, that can be readily used in
 62 radiation hydrodynamics codes. These files are especially lightweight: a typical calculation
 63 involving $q \in [-4.5, -2.5]$ with $\Delta q = 0.25$, $a_{\max} \in [0.1 \mu\text{m}, 1 \text{ m}]$ sampled twice per decade,
 64 and $T \in [1, 2000] \text{ K}$ with 100 points results in two arrays of $9 \times 15 \times 100$ elements, or
 65 about 220 kB of memory. This choice of spacing means that opacities are exactly evaluated
 66 for $q \in [-3.75, -3.5, -3]$, corresponding to dust size distributions in equilibrium due to
 67 small/large-scale turbulence, radial drift, or in a non-equilibrium growth regime. For more
 68 information, see [[@PfeilEtal:2024](#)].

69 The code and documentation are available at
 70 <https://github.com/alexziab/growpacity>.

71 Limitations and extensions

72 We underscore that our intent is not to provide a new or more realistic dust opacity model,
 73 but rather one suitable for use in coagulation models, where dust densities and distributions
 74 can vary as a function of position and time—the applicability of the model depends on
 75 entirely user-defined choices. The method can be easily extended to include gas opacities
 76 [[@SemenovEtal:2003](#); [@MalyginEtal:2014](#)] and prescriptions for the sublimation of dust
 77 species [[@IsellaNatta:2005](#)], for a more complete opacity model in regimes where gas
 78 opacities are significant.
